LECTURE 8  Two-dimensional (Plane) Stress State. Graphical Method of Stress State Analysis

1  Two-Dimensional (Plane) Stress State Definition and Examples

A two-dimensional (plane) state of stress exists at a point of deformable solid, when the stresses are independent of one of the three coordinate axis. It means that the general feature of this type of stress state is the presence of one zero principal plane. Examples include the stresses arising on inclined sections of an axially loaded rod (Fig. 1), a shaft in torsion (Fig. 2), a beam at combined loading (Fig. 3), thin-walled vessel under internal pressure $p$ (Fig. 4), aircraft wind skin (Fig. 5), scoop box (Fig. 6).

![Two-dimensional stresses on inclined section in axial loading](image)

![Plane stress state at surface points of the shaft in torsion](image)

![Plane stress state at the surface point of a bar under combined loading](image)
Two-dimensional problems are of two classes: **plane stress** and **plane strain**. The condition that occurs in a thin plate subjected to loading uniformly distributed over the thickness and parallel to the plane of plate typifies the **state of plane stress** (plane stressed state, plane stress) (Fig. 7). Because the plate is thin, the stress-distribution may be closely approximated by assuming that two-dimensional stress
components do not vary throughout the thickness and the other components are zero. Another case of plane stress exists on the free surface of a structural or machine component (see Figs. 2, 3, 5, 6).

To explain plane stress, we will consider the stress element shown in Fig. 8. This element is infinitesimal in size and can be sketched either as a cube or as a rectangular parallelepiped.

![Elements in plane stress](image)

Fig. 8 Elements in plane stress: (a) three-dimensional view of an element oriented to the $x$, $y$, $z$ axes, (b) two-dimensional view of the same element, and (c) two-dimensional view of an element oriented to the $x_1$, $y_1$, $z_1$ axes

The $xyz$ axes are parallel to the edges of the element, and the faces of the element are designated by the directions of their outward normals. For instance, the right-hand face of the element is referred to as the positive $y$ face, and the left-hand face (hidden from the viewer) is referred to as the negative $y$ face. Similarly, the top face is the positive $z$ face, and the front face is the positive $x$ face.

When the material is in plane stress in the $yz$ plane, only the $y$ and $z$ faces of the element are subjected to stresses, and all stresses act parallel to the $y$ and $z$ axes, as shown in Fig. 8a. This stress condition is very common because it exists at the surface of any stressed body, except at points where external loads act on the surface. When the element shown in Fig. 8a is located at the free surface of a body, the $x$ face is in the plane of the surface (no stresses) and the $x$ axis is normal to the surface. This face may be considered as zero principal plane (see Fig. 5).
The symbols for the stresses shown in Fig. 8a have the following meanings. A normal stress $\sigma$ has a subscript that identifies the face on which the stress acts; for instance, the stress $\sigma_y$ acts on the $y$ face of the element and the stress $\sigma_z$ acts on the $z$ face of the element. *Since the element is infinitesimal in size, equal normal stresses act on the opposite faces.* The sign convention for normal stresses is the familiar one, namely, tension is positive and compression is negative.

A shear stress $\tau$ has two subscripts – the first subscript denotes the normal to the face on which the stress acts, and the second gives the direction on that face. Thus, the stress $\tau_{yz}$ acts on the $y$ face in the direction of the $z$ axis (Fig. 8a), and stress $\tau_{zy}$ acts on the $z$ face in the direction of the $y$ axis.

The sign convention for shear stresses is as follows. A *shear stress is positive when it acts on a positive face of an element in the positive direction of an axis, and it is negative when it acts on a positive face of an element in the negative direction of an axis.* Therefore, the stresses $\tau_{yz}$ and $\tau_{zy}$ shown on the positive $y$ and $z$ faces in Fig. 8a are positive shear stresses. Similarly, on a negative face of the element, a shear stress is positive when it acts in the negative direction of an axis. Hence, the stresses $\tau_{yz}$ and $\tau_{zy}$ shown on the negative $y$ and $z$ faces of the element are also positive.

The preceding sign convention for shear stresses is dependable on the equilibrium of the element, because we know that shear stresses on opposite faces of an infinitesimal element must be equal in magnitude and opposite in direction. Hence, according to our sign convention, a positive stress $\tau_{yz}$ acts upward on the positive face (Fig. 8a) and downward on the negative face. In a similar manner, the stresses $\tau_{zy}$ acting on the top and bottom faces of the element are positive although they have opposite directions.

We know that shear stresses on mutually perpendicular planes are equal in magnitude and have directions such that *both stresses point toward, or both point away from, the line of intersection of the faces.* Inasmuch as $\tau_{yz}$ and $\tau_{zy}$ are positive in the
directions shown in the Fig. 8, they are consistent with this observation. Therefore, we note that

\[ \tau_{yz} = \tau_{zy}. \]  

(1)

This equation was called earlier the **law of equality for shear stresses**. It was derived from equilibrium of the element.

For convenience in sketching plane-stress elements, we usually draw only a two-dimensional view of the element, as shown in Fig. 8b.

### 2 Stresses on Inclined Planes

Our goal now is to consider the stresses acting on inclined sections, assuming that the stresses \( \sigma_y, \sigma_z, \) and \( \tau_{yz} \) (Figs. 8a and b) are known. To determine the stresses acting on an inclined section at positive (counterclockwise) \( \alpha \)-angle, we consider a new stress element (Fig. 8c) that is located at the same point in the material as the original element (Fig. 8b). However, the new element has faces that are parallel and perpendicular to the inclined direction. Associated with this new element are axes \( y_1, \) \( z_1 \) and \( x_1 \) such that the \( x_1 \) axis coincides with the \( x \) axis and the \( y_1, z_1 \) **axes are rotated counterclockwise through an angle \( \alpha \) with respect to the \( yz \) axes**. The normal and shear stresses acting on this new element are denoted \( \sigma_{y_1}, \sigma_{z_1}, \tau_{y_1z_1}, \) and \( \tau_{z_1y_1}, \) using the same subscript designations and sign conventions described above for the stresses acting on the \( yz \) element. The previous conclusions regarding the shear stresses still apply, so that

\[ \tau_{y_1z_1} = \tau_{z_1y_1}. \]  

(2)

Note, that more simple designation of the stresses on inclined faces is used: \( \sigma_{y_1} = \sigma_\alpha, \) \( \sigma_{z_1} = \sigma_\beta, \) \( \tau_{yz} = \tau_\alpha, \) \( \tau_{zy} = \tau_\beta. \)

From Eq. 2 and the equilibrium of the element, we see that the **shear stresses acting on all four side faces of an element in plane stress are known if we determine the shear stress acting on any one of those faces.**
The stresses acting on the inclined \( y_1, z_1 \) element (Fig. 8c) can be expressed in terms of the stresses on the \( yz \) element (Fig. 8b) by using equations of equilibrium. For this purpose, we choose a wedge-shaped stress element (Fig. 9a) having an inclined face that is the same as the \( y_1 \) face of the inclined element. The other two side faces of the wedge are parallel to the \( y \) and \( z \) axes.

![Wedge-shaped stress element](image)

Fig. 9 Wedge-shaped stress element in plane stress state: (a) stresses acting on the element, and (b) internal forces acting on the element

In order to write equations of equilibrium for the wedge, we need to construct a free-body diagram showing the forces acting on the faces. Let us denote the area of the left-hand side face (that is, the negative \( y \) face) as \( A_0 \). Then the normal and shear forces acting on that face are \( \sigma_y A_0 \) and \( \tau_{yz} A_0 \), as shown in the free-body diagram of Fig. 9b. The area of the bottom face (or negative \( z \) face) is \( A_0 \tan \alpha \), and the area of the inclined face (or positive \( y_1 \) face) is \( A_0 \sec \alpha \). Thus, the normal and shear forces acting on these faces have the magnitudes and directions shown in the Fig. 9b.

The forces acting on the left-hand and bottom faces can be resolved into orthogonal components acting in the \( y_1 \) and \( z_1 \) directions. Then we can obtain two
equations of equilibrium by summing forces in those directions. The first equation, obtained by summing forces in the $y_1$ direction, is

$$\sigma_{y_1}A_0 \sec \alpha - \sigma_y A_0 \cos \alpha - \tau_{yz}A_0 \sin \alpha - -\sigma_z A_0 \tan \alpha \sin \alpha - \tau_{zy}A_0 \tan \alpha \cos \alpha = 0. \quad (3)$$

Summation of forces in the $y_1$ direction gives

$$\tau_{y_1z_1} A_0 \sec \alpha + \sigma_y A_0 \sin \alpha - \tau_{yz} A_0 \cos \alpha - -\sigma_z A_0 \tan \alpha \cos \alpha + \tau_{zy} A_0 \tan \alpha \sin \alpha = 0. \quad (4)$$

Using the relationship $\tau_{yz} = \tau_{zy}$, we obtain after simplification the following two equations:

$$\sigma_{y_1} = \sigma_y \cos^2 \alpha + \sigma_z \sin^2 \alpha + 2\tau_{yz} \sin \alpha \cos \alpha, \quad (5)$$

$$\tau_{y_1z_1} = -(\sigma_y - \sigma_z) \sin \alpha \cos \alpha + \tau_{yz} \left(\cos^2 \alpha - \sin^2 \alpha\right). \quad (6)$$

Equations (5) and (6) give the normal and shear stresses acting on the $y_1$ plane in terms of the angle $\alpha$ and the stresses $\sigma_y$, $\sigma_z$, and $\tau_{yz}$ acting on the $y$ and $z$ planes. Due to $\sigma_{y_1}$ and $\tau_{y_1z_1}$ are applied to the inclined face at the $\alpha$ angle relative to $y$ direction, it is convenient to designate, that

$$\sigma_{y_1} = \sigma_y \quad \text{and} \quad \tau_{y_1z_1} = \tau_{yz}. \quad (7)$$

It is interesting to note, that in $\alpha = 0$ Eqs. (5) and (6) give $\sigma_{y_1} = \sigma_y$ and $\tau_{y_1z_1} = \tau_{yz}$. Also, when $\alpha = 90^\circ$, these equations give $\sigma_{y_1} = \sigma_z$ and $\tau_{y_1z_1} = -\tau_{yz} = -\tau_{zy}$. In the latter case, since the $y_1$ axis is vertical when $\alpha = 90^\circ$, the stress $\tau_{y_1z_1}$ will be positive when it acts to the left. However, the stress $\tau_{zy}$ acts to the right, and therefore $\tau_{y_1z_1} = -\tau_{zy}$.

Equations (5) and (6) can be expressed in a more convenient form by introducing the following trigonometric identities:
\[
\cos^2 \alpha = \frac{1}{2}(1 + \cos 2\alpha), \quad \sin^2 \alpha = \frac{1}{2}(1 - \cos 2\alpha), \quad \sin \alpha \cos \alpha = \frac{1}{2}\sin 2\alpha .
\]

(8)

After these substitutions the equations become

\[
\sigma_{y_1} = \frac{\sigma_y + \sigma_z}{2} + \frac{\sigma_y - \sigma_z}{2}\cos 2\alpha + \tau_{yz}\sin 2\alpha .
\]

(9)

\[
\tau_{y_1z_1} = -\frac{\sigma_y - \sigma_z}{2}\sin 2\alpha + \tau_{yz}\cos 2\alpha .
\]

(10)

These equations are known as the transformation equations for plane stress because they transform the stress components from one set of axes to another.

**Note.** (1) Only one intrinsic state of stress exists at the point in a stressed body, regardless of the orientation of the element, i.e. whether represented by stresses acting on the \(yz\) element (Fig. 8b) or by stresses acting on the inclined \(y_1z_1\) element (Fig. 8c). (2) Since the transformation equations were derived only from equilibrium of an element, they are applicable to stresses in any kind of material, whether linear or nonlinear, elastic or inelastic.

An important result concerning the normal stresses can be obtained from the transformation equations. The normal stress \(\sigma_{z_1}\) acting on the \(z_1\) face of the inclined element (Fig. 8c) can be obtained from Eq. (9) by substituting \(\alpha + 90^\circ\) for \(\alpha\). The result is the following equation for \(\sigma_{z_1}\): 

\[
\sigma_{z_1} = \frac{\sigma_y + \sigma_z}{2} - \frac{\sigma_y - \sigma_z}{2}\cos 2\alpha - \tau_{yz}\sin 2\alpha .
\]

(11)

Summing the expressions for \(\sigma_{y_1}\) and \(\sigma_{z_1}\) (Eqs. (9) and (11)), we obtain the following equation for plane stress:

\[
\sigma_{y_1} + \sigma_{z_1} = \sigma_y + \sigma_z = \text{const} .
\]

(12)

**Note.** The sum of the normal stresses acting on perpendicular faces of plane-stress elements (at a given point in a stressed body) is constant and independent on the angle \(\alpha\).
The graphs of the normal and shear stresses varying are shown in Fig. 10, which are the graphs of $\sigma_{y_1}$ and $\tau_{y_1z_1}$ versus the angle $\alpha$ (from Eqs. 9 and 10). The graphs are plotted for the particular case of $\sigma_z = 0.2\sigma_y$ and $\tau_{yz} = 0.8\sigma_y$. It is seen from the plots that the stresses vary continuously as the orientation of the element is changed. At certain angles, the normal stress reaches a maximum or minimum value; at other angles, it becomes zero. Similarly, the shear stress has maximum, minimum, and zero values at certain angles.

![Graph of normal and shear stresses](image)

**Fig. 10** Graphs of normal stress $\sigma_{y_1}$ and shear stress $\tau_{y_1z_1}$ versus the angle $\alpha$ (for particular case: $\sigma_z = 0.2\sigma_y$ and $\tau_{yz} = 0.8\sigma_y$)

### 3 Special Cases of Plane Stress

#### 3.1 Uniaxial Stress State as a Simplified Case of Plane Stress

The general case of plane stress reduces to simpler states of stress under special conditions. For instance, as previously discussed, if all stresses acting on the $yz$ element (Fig. 8b) are zero except for the normal stress $\sigma_y$, then the element is in uniaxial stress (Fig. 11). The corresponding transformation...
equations, obtained by setting $\sigma_z$ and $\tau_{yz}$ equal to zero in Eqs. (9) and (10), are

\[
\sigma_{y_1} = \frac{\sigma_y}{2}(1 + \cos 2\alpha) = \sigma_y \cos^2 \alpha ,
\]

(13)

\[
\tau_{y_1z_1} = -\frac{\sigma_y}{2}(\sin 2\alpha).
\]

(14)

Note, that this type of stress state corresponds to axial tension deformation (see Fig. 1)

3.2 Pure Shear as a Special Case of Plane Stress

**Pure shear** is another special case of plane stress state (Fig. 12), for which the transformation equations are obtained by substituting $\sigma_y = 0$ and $\sigma_z = 0$ into Eqs. (9) and (10):

\[
\sigma_{y_1} = \tau_{yz} \sin 2\alpha , \quad (15)
\]

\[
\tau_{y_1z_1} = \tau_{yz} \cos 2\alpha . \quad (16)
\]

3.3 Biaxial Stress

The next special case of plane stress state is called **biaxial stress**, in which the $yz$ element is subjected to normal stresses in both the $y$ and $z$ directions but without any shear stresses (Fig. 13). The equations for biaxial stress are obtained from Eqs. (9) and (10) by dropping the terms containing $\tau_{yz}$:

\[
\sigma_{y_1} = \frac{\sigma_y + \sigma_z}{2} + \frac{\sigma_y - \sigma_z}{2} \cos 2\alpha ,
\]

(17)

\[
\tau_{y_1z_1} = -\frac{\sigma_y - \sigma_z}{2} \sin 2\alpha .
\]

(18)

or in $\alpha, \beta$ designation,

\[
\sigma_{y_1} = \sigma_y \cos^2 \alpha + \sigma_z \sin^2 \alpha ,
\]

(19)
\[ \tau_{y_1z_1} = -\frac{1}{2} (\sigma_y - \sigma_z) \sin 2\alpha . \] (20)

Biaxial stress occurs in many kinds of structures, including thin-walled pressure vessels (see Fig. 14).

**Example 1**

The state of stress at a point in the machine element is shown in Fig. a. Determine the normal and shearing stresses acting on an inclined plane parallel to (1) line \(a - a\) and (2) line \(b - b\).

![Diagram](image_url)

**Solution**  The \(x_1\) direction is that of a normal to the inclined plane. We want to obtain the transformation of stress from the \(xy\) system of coordinates to the \(x_1y_1\) system.
Note, that the stresses and the rotations must be designated with their correct signs.

(1) Applying Eqs. (9 through 11) for $\alpha = 45^\circ$, $\sigma_x = 10$ MPa, $\sigma_y = -5$ MPa, and $\tau_{xy} = -6$ MPa, we obtain

$$\sigma_{x_1} = \frac{1}{2}(10 - 5) + \frac{1}{2}(10 + 5) \cos 90^\circ - 6 \sin 90^\circ = -3.5 \text{ MPa},$$

$$\tau_{x_1y_1} = -\frac{1}{2}(10 + 5) \sin 90^\circ - 6 \cos 90^\circ = -7.5 \text{ MPa},$$

and

$$\sigma_{y_1} = \frac{1}{2}(10 - 5) - \frac{1}{2}(10 + 5) \cos 90^\circ + 6 \sin 90^\circ = 8.5 \text{ MPa}.$$

The results are indicated in Fig. b.

(2) As $\alpha = 30 + 90 = 120^\circ$, from Eqs. (9 through 11), we have

$$\sigma_{x_1} = \frac{1}{2}(10 - 5) + \frac{1}{2}(10 + 5) \cos 240^\circ - 6 \sin 240^\circ = 3.95 \text{ MPa},$$

$$\tau_{x_1y_1} = -\frac{1}{2}(10 + 5) \sin 240^\circ - 6 \cos 240^\circ = 9.5 \text{ MPa},$$

and

$$\sigma_{y_1} = \frac{1}{2}(10 - 5) - \frac{1}{2}(10 + 5) \cos 240^\circ + 6 \sin 240^\circ = 1.05 \text{ MPa}.$$

The results are indicated in Fig. c.

**Example 2**

A two-dimensional stress state at a point in a loaded structure is shown in Fig. a.

(1) Write the stress-transformation equations. (2) Compute $\sigma_{x_1}$ and $\tau_{x_1y_1}$ with $\alpha$ between 0 and $180^\circ$ in $15^\circ$ increments for $\sigma_x = 7$ MPa, $\sigma_y = 2$ MPa, and $\tau_{xy} = 5$ MPa. Plot the graphs $\sigma_{x_1}(\alpha)$ and $\tau_{x_1y_1}(\alpha)$. 
Variation in normal stress $\sigma_{x_1}$ and shearing stress $\tau_{x_1y_1}$ with angle $\alpha$ varying between 0 and 180°

**Solution** (1) We express Eqs. (9) and (10) as follows:

$$\sigma_{x_1} = A + B\cos 2\alpha + C\sin 2\alpha,$$
$$\tau_{x_1y_1} = -B\sin 2\alpha + C\cos 2\alpha,$$

where

$$A = \frac{1}{2}(\sigma_x + \sigma_y), \quad B = \frac{1}{2}(\sigma_x - \sigma_y), \quad C = \tau_{xy}.$$ 

(2) Substitution of the prescribed values into Eqs. (9) and (10) results in

$$\sigma_{x_1} = 4.5 + 2.5\cos 2\alpha + 5\sin 2\alpha,$$
$$\tau_{x_1y_1} = -2.5\sin 2\alpha + 5\cos 2\alpha.$$ 

Here, permitting $\alpha$ to vary from 0 to 180° in increments of 15° yields the data upon which the curves shown in Fig. b are based. These cartesian representations indicate how the stresses vary around a point. Observe that the **direction of maximum (and minimum) shear stress bisects the angle between the maximum and minimum normal stresses**. Moreover, the normal stress is either a maximum or a minimum on planes $\alpha = 31.7^\circ$ and $\alpha = 31.7^\circ + 90^\circ$, respectively, for which the shearing stress is
Note. The conclusions drawn from the foregoing are valid for any state of stress.

Example 3

An element in plane stress is subjected to stresses \( \sigma_x = 110.32 \, \text{MPa} \), \( \sigma_y = 41.37 \, \text{MPa} \), and \( \tau_{xy} = \tau_{yx} = 27.58 \, \text{MPa} \), as shown in Fig. a. Determine the stresses acting on an element inclined at an angle \( \alpha = 45^\circ \).

![Diagram](image)

(a) Element in plane stress, and (b) element inclined at an angle \( \alpha = 45^\circ \)

Solution To determine the stresses acting on an inclined element, we will use the transformation equations (Eqs. (9) and (10)). From the given numerical data, we obtain the following values for substitution into those equations:

\[
\frac{\sigma_x + \sigma_y}{2} = 75.845 \, \text{MPa}, \quad \frac{\sigma_x - \sigma_y}{2} = 34.475 \, \text{MPa}, \quad \tau_{xy} = 27.58 \, \text{MPa},
\]

\[
\sin 2\alpha = \sin 90^\circ = 1, \quad \cos 2\alpha = \cos 90^\circ = 0.
\]

Substituting these values into Eqs. (9) and (10), we get

\[
\sigma_{x_1} = \frac{\sigma_x + \sigma_y}{2} + \frac{\sigma_x - \sigma_y}{2} \cos 2\alpha + \tau_{xy} \sin 2\alpha =
\]

\[
= 75.845 \, \text{MPa} + (34.475 \, \text{MPa})(0) + (27.58 \, \text{MPa})(1) = 103.425 \, \text{MPa},
\]

\[
\tau_{x_1 y_1} = -\frac{\sigma_x - \sigma_y}{2} \sin 2\alpha + \tau_{xy} \cos 2\alpha =
\]
\[
\sigma_y = \left( \frac{\sigma_x + \sigma_y}{2} - \frac{\sigma_x - \sigma_y}{2} \right) \cos 2\alpha - \tau_{xy} \sin 2\alpha = 75.845 \text{ MPa} - (34.475 \text{ MPa})(0) - (27.58 \text{ MPa})(1) = 48.265 \text{ MPa}.
\]

From these results we can obtain the stresses acting on all sides of an element oriented at \( \alpha = 45^\circ \), as shown in Fig. b. The arrows show the true directions in which the stresses act. Note especially the directions of the shear stresses, all of which have the same magnitude. Also, observe that the sum of the normal stresses remains constant and equal to 151.69 MPa from Eq. (12):

\[
\sigma_{x1} + \sigma_{y1} = \sigma_x + \sigma_y = 151.69 \text{ MPa}.
\]

Note. The stresses shown in Fig. b represent the same intrinsic state of stress as do the stresses shown in Fig. a. However, the stresses have different values because the elements on which they act have different orientations.

Example 4

On the surface of a loaded structure a plane stress state exists at a point, where the stresses have the magnitudes and directions shown on the stress element of Fig. a. Determine the stresses acting on an element that is oriented at a clockwise angle of 15° with respect to the original element.
Solution  The stresses acting on the original element (see Fig. a) have the following values:

\[ \sigma_x = -46 \text{ MPa}, \quad \sigma_y = 12 \text{ MPa}, \quad \tau_{xy} = -19 \text{ MPa}. \]

An element oriented at a clockwise angle of 15° is shown in Fig. b, where the \( x_1 \) axis is at an angle \( \alpha = -15^\circ \) with respect to the \( x \) axis (clockwised rotation).

We will calculate the stresses on the \( x_1 \) face of the element oriented at \( \alpha = -15^\circ \) by using the transformation equations (Eqs. (9) and (10)). The components are:

\[
A = \frac{\sigma_x + \sigma_y}{2} = -17 \text{ MPa}, \quad B = \frac{\sigma_x - \sigma_y}{2} = -29 \text{ MPa},
\]

\[
sin 2\alpha = \sin(-30^\circ) = -0.5, \quad \cos 2\alpha = \cos(-30^\circ) = 0.8660.
\]

Substituting into the transformation equations, we get

\[
\sigma_{x_1} = \frac{\sigma_x + \sigma_y}{2} + \frac{\sigma_x - \sigma_y}{2} \cos 2\alpha + \tau_{xy} \sin 2\alpha =
\]

\[= -17 \text{ MPa} + (-29 \text{ MPa})(0.8661) + (-19 \text{ MPa})(-0.5) = -32.6 \text{ MPa},
\]

\[
\tau_{x_1y_1} = -\frac{\sigma_x - \sigma_y}{2} \sin 2\alpha + \tau_{xy} \cos 2\alpha =
\]

\[= -(-29 \text{ MPa})(-0.5) + (-19 \text{ MPa})(0.8660) = -31.0 \text{ MPa}.
\]

Also, the normal stress acting on the \( y_1 \) face (Eq. (3.10)) is

\[
\sigma_{y_1} = \frac{\sigma_x + \sigma_y}{2} - \frac{\sigma_x - \sigma_y}{2} \cos 2\alpha - \tau_{xy} \sin 2\alpha =
\]

\[= -17 \text{ MPa} - (-29 \text{ MPa})(0.8661) - (-19 \text{ MPa})(-0.5) = -1.4 \text{ MPa}.
\]

To check the results, we note that \( \sigma_{x_1} + \sigma_{y_1} = \sigma_x + \sigma_y \).

The stresses acting on the inclined element are shown in Fig. b, where the arrows indicate the true directions of the stresses.

Note. Both stress elements shown in the figure represent the same state of stress.
4 Principal Stresses and Maximum Shear Stresses

The transformation equations for plane stress show that the normal stresses $\sigma_{y_1}$ and the shear stresses $\tau_{y_1z_1}$ vary continuously as the axes are rotated through the angle $\alpha$. This variation is pictured in Fig. 10 for a particular combination of stresses. From the figure, we see that both the normal and shear stresses reach maximum and minimum values at $90^\circ$ intervals. These maximum and minimum values are usually needed for design purposes. For instance, fatigue failures of structures such as machines and aircraft are often associated with the maximum stresses, and hence their magnitudes and orientations should be determined as part of the design process.

The determination of principal stresses is an example of a type of mathematical analysis known as eigenvalue problem in matrix algebra. The stress-transformation equations and the concept of principal stresses are due to the French mathematicians A. L. Cauchy (1789–1857) and Barre de Saint-Venant (1797–1886) and to the Scottish scientist and engineer W. J. M. Rankine (1820–1872).

4.1 Principal Stresses

The maximum and minimum normal stresses, called the principal stresses, can be found from the transformation equation for the normal stress $\sigma_{y_1}$ (Eq. 9). By taking the derivative of $\sigma_{y_1}$ with respect to $\alpha$ and setting it equal to zero, we obtain an equation from which we can find the values of at which $\sigma_{y_1}$ is a maximum or minimum. The equation for the derivative is

$$\frac{d\sigma_{y_1}}{d\alpha} = -(\sigma_y - \sigma_z)\sin 2\alpha + 2\tau_{yz}\cos 2\alpha = 0,$$

from which we get

$$\tan 2\alpha_p = \frac{2\tau_{yz}}{\sigma_y - \sigma_z},$$

or in more simple designation,
The subscript $p$ indicates that the angle $\alpha_p$ defines the orientation of the principal planes, i.e. the planes, on which the principal stresses act.

Two values of the angle $2\alpha_p$ in the range from 0 to 360° can be obtained from Eq. (22). These values differ by 180°, with one value between 0 and 180° and the other between 180° and 360°. Therefore, the angle $\alpha_p$ has two values that differ by 90°, one value between 0 and 90° and the other between 90° and 180°. The two values of $\alpha_p$ are known as the principal angles. For one of these angles, the normal stress $\sigma_{y_1}$ is a maximum principal stress; for the other, it is a minimum principal stress. Because the principal angles differ by 90°, we see that the principal stresses occur on mutually perpendicular planes.

The principal stresses can be calculated by substituting each of the two values of $\alpha_p$ into the first stress-transformation equation (Eq. 9) and solving for $\sigma_{y_1}$. By determining the principal stresses in this manner, we not only obtain the values of the principal stresses but we also learn which principal stress is associated with which principal angle.

Let us obtain the formulas for the principal stresses, using right triangle in Fig. 15, constructed from Eq. (22). The hypotenuse of the triangle, obtained from the Pythagorean theorem, is

$$R = \sqrt{\left(\frac{\sigma_y - \sigma_z}{2}\right)^2 + \tau_{yz}^2}.$$  \hspace{1cm} (24)

The quantity $R$ is always a positive number and, like the other two sides of the triangle, has units of stress. From the triangle we obtain two additional relations:
\[ \cos 2\alpha_p = \frac{\sigma_y - \sigma_z}{2R}, \]  
\hspace{2cm} (25) 
\[ \sin 2\alpha_p = \frac{\tau_{yz}}{R}. \]  
\hspace{2cm} (26) 

Now we substitute these expressions for \( \cos 2\alpha_p \) and \( \sin 2\alpha_p \) into Eq. (9) and obtain the algebraically larger of the two principal stresses, denoted by \( \sigma_1 \): 
\[ \sigma_1 = \frac{\sigma_y + \sigma_z}{2} + \sqrt{\left( \frac{\sigma_y - \sigma_z}{2} \right)^2 + \tau_{yz}^2}. \]  
\hspace{2cm} (27) 

The smaller of the principal stresses, denoted by \( \sigma_3 \), may be found from the condition that the sum of the normal stresses on perpendicular planes is constant (see Eq. 12): 
\[ \sigma_1 + \sigma_3 = \sigma_y + \sigma_z. \]  
\hspace{2cm} (28) 

Substituting the expression for \( \sigma_1 \) into Eq. (28) and solving for \( \sigma_3 \), we get 
\[ \sigma_3 = \frac{\sigma_y + \sigma_z}{2} - \sqrt{\left( \frac{\sigma_y - \sigma_z}{2} \right)^2 + \tau_{yz}^2}. \]  
\hspace{2cm} (29) 

The formulas for \( \sigma_1 \) and \( \sigma_3 \) can be combined into a single formula for the principal stresses: 
\[ \sigma_{\text{max, min}} = \sigma_{1, 3} = \frac{\sigma_y + \sigma_z}{2} \pm \sqrt{\left( \frac{\sigma_y - \sigma_z}{2} \right)^2 + \tau_{yz}^2}. \]  
\hspace{2cm} (30) 

Note. The plus sign gives the algebraically larger principal stress and the minus sign gives the algebraically smaller principal stress.

Let us now find two angles defining the principal planes as \( \alpha_{p1} \) and \( \alpha_{p2} \), corresponding to the principal stresses \( \sigma_1 \) and \( \sigma_3 \), respectively. Both angles can be determined from the equation for \( \tan 2\alpha_p \) (Eq. 22). To correlate the principal angles
and principal stresses we will use Eqs. (25) and (26) to find $\alpha_p$ since the only angle that satisfies both of those equations is $\alpha_{p1}$. Thus, we can rewrite those equations as follows:

$$\cos 2\alpha_{p1} = \frac{\sigma_y - \sigma_z}{2R},$$  \hspace{1cm} (31)\\
$$\sin 2\alpha_{p1} = \frac{\tau_{yz}}{R}.\hspace{1cm} (32)$$

Only one angle exists between 0 and 360° that satisfies both of these equations. Thus, the value of $\alpha_{p1}$ can be determined uniquely from Eqs. (31) and (32). The angle $\alpha_{p2}$, corresponding to $\sigma_3$, defines a plane that is perpendicular to the plane defined by $\alpha_{p1}$. Therefore, $\alpha_{p2}$ can be taken as 90° larger or 90° smaller than $\alpha_{p1}$.

It is very important to evaluate the value of shear stresses acting at principal planes since it was noted earlier that they are zero. For this purpose, we will use the transformation equation for the shear stresses (Eq. (10)). If we set the shear stress $\tau_{y_1z_1}$ equal to zero, we get an equation that is the same as Eq. (21). It means that the **angles to the planes of zero shear stress are the same as the angles to the principal planes**. Thus, **the shear stresses are zero on the principal planes**.

The principal planes for elements in **uniaxial stress** and **biaxial stress** are the $y$ and $z$ planes themselves (Fig. 16), because $\tan 2\alpha_p = 0$ (see Eq. 22) and the two values of $\alpha_p$ are 0 and 90°. We also know that the $y$ and $z$ planes are the principal planes from the fact that the shear stresses are zero on those planes.
Fig. 16 Elements in uniaxial (a) and (b) and biaxial (c), (d), (e) stress state:
(a) $\sigma_y = 80 \text{ MPa} = \sigma_1$, $\sigma_z = 0 = \sigma_2(3)$, $\sigma_x = 0 = \sigma_3(2)$;
(b) $\sigma_y = -80 \text{ MPa} = \sigma_3$, $\sigma_z = 0 = \sigma_1(2)$, $\sigma_x = 0 = \sigma_2(1)$;
(c) $\sigma_y = 60 \text{ MPa} = \sigma_1$, $\sigma_z = 25 \text{ MPa} = \sigma_2$, $\sigma_x = 0 = \sigma_3$;
(d) $\sigma_y = -60 \text{ MPa} = \sigma_3$, $\sigma_z = 25 \text{ MPa} = \sigma_1$, $\sigma_x = 0 = \sigma_2$;
(e) $\sigma_y = -60 \text{ MPa} = \sigma_3$, $\sigma_z = -25 \text{ MPa} = \sigma_2$, $\sigma_x = 0 = \sigma_1$

For an element in pure shear (Fig. 17a), the principal planes are oriented at 45° to the y axis (Fig. 17b), because $\tan 2\alpha_p$ is infinite and the two values of $\alpha_p$ are 45° and 135°. If $\tau_{yz}$ is positive, the principal stresses are $\sigma_1 = \tau_{yz}$ and $\sigma_3 = -\tau_{yz}$.
Two principal stresses determined from Eq. (30) are called the **in-plane principal stresses**, since they refer only to rotation of axes in the \(zy\) plane, that is rotation about the \(x\) axis. Really any stress element is three-dimensional (Fig. 18a) and has three (not two) principal stresses acting on three mutually perpendicular planes. By making a more complete three-dimensional analysis, it can be shown that the three principal planes for a plane-stress element are the two principal planes already described plus the \(x\) face of the element. These principal planes are shown in Fig. 18b, where a stress element has been oriented at the principal angle \(\theta_{p1}\) which corresponds to the principal stress \(\sigma_1\). The principal stresses \(\sigma_1\) and \(\sigma_2\) are given by Eq. (30), and the third principal stress \((\sigma_3)\) equals zero. By definition, \(\sigma_1\) is algebraically the largest and \(\sigma_3\) is algebraically the smallest one.

**Note.** There are no shear stresses on any of the principal planes.

![Diagram](image)

**Fig. 18** Elements in plane stress: (a) original element, and (b) element oriented to the three principal planes and three principal stresses

### 4.2 Maximum Shear Stresses

Now we consider the determination of the maximum shear stresses and the planes on which they act. The shear stresses \(\tau_{y_1z_1}\) acting on inclined planes are given
by the second transformation equation (Eq. 10). Equating the derivative of $\tau_{y_1z_1}$ with respect to $\alpha$ to zero, we obtain

$$\frac{d\tau_{y_1z_1}}{d\alpha} = -\left(\sigma_y - \sigma_z\right)\cos 2\alpha - 2\tau_{yz}\sin 2\alpha = 0,$$

from which

$$\tan 2\alpha_s = -\frac{\sigma_y - \sigma_z}{2\tau_{yz}}. \quad (34)$$

The subscript $s$ indicates that the angle $\alpha_s$ defines the orientation of the planes of maximum positive and negative shear stresses. Equation (34) yields one value of $\alpha_s$ between 0 and 90° and another between 90° and 180°. These two values differ by 90°, and therefore the maximum shear stresses occur on perpendicular planes. Because shear stresses on perpendicular planes are equal in absolute value, the maximum positive and negative shear stresses differ only in sign.

Comparing Eq. (34) for $\alpha_s$ with Eq. (22) for $\alpha_p$ shows that

$$\tan 2\alpha_s = -\frac{1}{\tan 2\alpha_p} = -\cot 2\alpha_p. \quad (35)$$

This equation is the relationship between the angles $\alpha_s$, and $\alpha_p$. Let us rewrite this equation in the form

$$\frac{\sin 2\alpha_s}{\cos 2\alpha_s} + \frac{\cos 2\alpha_p}{\sin 2\alpha_p} = 0, \quad (36)$$

or

$$\sin 2\alpha_s \sin 2\alpha_p + \cos 2\alpha_s \cos 2\alpha_p = 0. \quad (37)$$

Eq. (37) is equivalent to the following expression:

$$\cos\left(2\alpha_s - 2\alpha_p\right) = 0.$$

Therefore,
Note. Eq. (38) shows that the planes of maximum shear stress occur at 45° to the principal planes.

The plane of the maximum positive shear stress \( \tau_{\text{max}} \) is defined by the angle \( \alpha_{s_1} \), for which the following equations apply:

\[
\cos 2\alpha_{s_1} = \frac{\tau_{yz}}{R},
\]

(39)

\[
\sin 2\alpha_{s_1} = -\frac{\sigma_y - \sigma_z}{2R},
\]

(40)

in which \( R \) is given by Eq. (24). Also, the angle \( \alpha_{s_1} \) is related to the angle \( \alpha_{p_1} \) (see Eqs. (31) and (32)) as follows:

\[
\alpha_{s_1} = \alpha_{p_1} - 45^\circ.
\]

(41)

Corresponding maximum shear stress is obtained by substituting the expressions for \( \cos 2\alpha_{s_1} \) and \( \sin 2\alpha_{s_1} \) into the second transformation equation (Eq. 8), yielding

\[
\tau_{\text{max}} = \sqrt{\left(\frac{\sigma_y - \sigma_z}{2}\right)^2 + \tau_{yz}^2}.
\]

(42)

The maximum negative shear stress has the same magnitude but opposite sign.

Another expression for the maximum shear stress \( \tau_{\text{max}} \) can be obtained from the principal stresses \( \sigma_1 \) and \( \sigma_3 \), both of which are given by Eq. (30). Subtracting the expression for \( \sigma_3 \) from that for \( \sigma_1 \) and then comparing with Eq. (42), we see that

\[
\tau_{\text{max}} = \frac{\sigma_1 - \sigma_3}{2}.
\]

(43)
Note. Maximum shear stress is equal to one-half the difference of the principal stresses.

The planes of maximum shear stress $\tau_{\text{max}}$ also contain normal stresses. The normal stress acting on the planes of maximum positive shear stress can be determined by substituting the expressions for the angle $\alpha_{s1}$ (Eqs. (39) and (40)) into the equation for $\sigma_{y1}$ (Eq. 9). The resulting stress is equal to the average of the normal stresses on the $y$ and $z$ planes:

$$\sigma_{\text{aver}} = \frac{\sigma_y + \sigma_z}{2}. \quad (44)$$

This same normal stress acts on the planes of maximum negative shear stress.

In the particular cases of uniaxial stress and biaxial stress (Fig. 16), the planes of maximum shear stress occur at 45° to the $y$ and $z$ axes. In the case of pure shear (Fig. 17), the maximum shear stresses occur on the $y$ and $z$ planes.

The analysis of shear stresses has dealt only with the stresses acting in the $yz$ plane, i.e. in-plane shear stress. The maximum in-plane shear stresses were found on an element obtained by rotating the $x, y, z$ axes (Fig. 18a) about the $x_1$ axis through an angle of 45° to the principal planes. The principal planes for the element of Fig. 18a are shown in Fig. 18b.

We can also obtain maximum shear stresses by 45° rotations about the other two principal axes (the $y_1$ and $z_1$ axes in Fig. 18b). As a result, we obtain three sets of maximum positive and maximum negative shear stresses (compare with Eq. (43)).

**Example 5**

An element in plane stress is subjected to stresses $\sigma_x = 84.8 \text{ MPa}$, $\sigma_y = -28.9 \text{ MPa}$, and $\tau_{xy} = -32.4 \text{ MPa}$, as shown in Fig. a. (1) Determine the principal stresses and show them on a sketch of a properly oriented element; (2) Determine the maximum shear stresses and show them on a sketch of a properly oriented element.
Solution (1) *Calculation of principal stresses*. The principal angles $\alpha_p$ that locate the principal planes can be obtained from Eq. (22):

$$\tan 2\alpha_p = \frac{2\tau_{xy}}{\sigma_x - \sigma_y} = \frac{2(-32.4 \text{ MPa})}{84.8 \text{ MPa} - (-28.9 \text{ MPa})} = -0.5697.$$  

Solving for the angles, we get the following two sets of values:

$$2\alpha_p = 150.3^\circ \quad \text{and} \quad \alpha_p = 75.2^\circ,$$

$$2\alpha_p = 330.3^\circ \quad \text{and} \quad \alpha_p = 165.2^\circ.$$
The principal stresses may be obtained by substituting the two values of $2\alpha_p$ into the transformation equation for $\sigma_{x_1}$ (Eq. (9)). Determine preliminary the following quantities:

$$A = \frac{\sigma_x + \sigma_y}{2} = \frac{84.8 \text{ MPa} - 28.9 \text{ MPa}}{2} = 27.9 \text{ MPa},$$

$$B = \frac{\sigma_x - \sigma_y}{2} = \frac{84.8 \text{ MPa} + 28.9 \text{ MPa}}{2} = 56.8 \text{ MPa}.$$

Now we substitute the first value of $2\alpha_p$ into Eq. (9) and obtain

$$\sigma_{x_1} = \frac{\sigma_x + \sigma_y}{2} + \frac{\sigma_x - \sigma_y}{2}\cos 2\alpha + \tau_{xy}\sin 2\alpha =$$

$$= 27.9 \text{ MPa} + (56.8 \text{ MPa})(\cos 150.3^\circ) - (32.4 \text{ MPa})(\sin 150.3^\circ) = -37.5 \text{ MPa}.$$

By the similar way, we substitute the second value of $2\alpha_p$ and obtain $\sigma_{x_1} = 93.4 \text{ MPa}$. In result, the principal stresses and their corresponding principal angles are

$$\sigma_1 = 93.4 \text{ MPa} \quad \text{and} \quad \alpha_{p_1} = 165.2^\circ$$

$$\sigma_3 = -37.5 \text{ MPa} \quad \text{and} \quad \alpha_{p_2} = 75.2^\circ.$$

Keep in mind, that $\sigma_2 = 0$ acts in $z$ direction.

**Note,** that $\alpha_{p_1}$ and $\alpha_{p_2}$ differ by $90^\circ$ and that $\sigma_1 + \sigma_3 = \sigma_x + \sigma_y$.

The principal stresses are shown on a properly oriented element in the Fig. b. Of course, the principal planes are free from shear stresses.

The principal stresses may also be calculated directly from Eq. (30):

$$\sigma_{1,2(3)} = \frac{\sigma_x + \sigma_y}{2} \pm \sqrt{\left(\frac{\sigma_x - \sigma_y}{2}\right)^2 + \tau_{xy}^2} =$$

$$= 27.9 \text{ MPa} \pm \sqrt{(56.8 \text{ MPa})^2 + (-32.4 \text{ MPa})^2},$$

$$\sigma_{1,2(3)} = 27.9 \text{ MPa} \pm 65.4 \text{ MPa}.$$
Therefore,

\[ \sigma_1 = 93.4 \text{ MPa}, \sigma_3 = -37.5 \text{ MPa}, \ (\sigma_2 = 0). \]

(2) **Maximum shear stresses.** The maximum in-plane shear stresses are given by Eq. (42):

\[ \tau_{\text{max}} = \sqrt{\left(\frac{\sigma_x - \sigma_y}{2}\right)^2 + \tau_{xy}^2} = \sqrt{(56.8 \text{ MPa})^2 + (-32.4 \text{ MPa})^2} = 65.4 \text{ MPa}. \]

The angle \( \alpha_{s1} \) to the plane having the maximum positive shear stress is calculated from Eq. (41):

\[ \alpha_{s1} = \alpha_{p1} - 45^\circ = 165.2^\circ - 45^\circ = 120.2^\circ. \]

It follows that the maximum negative shear stress acts on the plane for which \( \alpha_{s2} = 120.2^\circ - 90^\circ = 30.2^\circ. \)

The normal stresses acting on the planes of maximum shear stresses are calculated from Eq. (44):

\[ \sigma_{\text{aver}} = \frac{\sigma_x + \sigma_y}{2} = 27.9 \text{ MPa}. \]

Finally, the maximum shear stresses and associated normal stresses are shown on the stress element of Fig. c.

5 **Circular Diagrams for Plane Stress (Mohr’s circles)**

The basic equations of stress transformation derived earlier may be interpreted graphically. The graphical technique permits the rapid transformation of stress from one plane to another and also provides an overview of the state of stress at a point. It provides a means for calculating principal stresses, maximum shear stresses, and stresses on inclined planes. This method was devised by the German civil engineer Otto Christian Mohr (1835–1918), who developed a plot known as **Mohr’s circle** in 1882. Mohr’s circle is valid not only for stresses, but also for other quantities of a similar nature, including strains and moments of inertia.
5.1 Equation of Mohr’s circle

The equations of Mohr’s circle can be derived from the transformation equations for plane stress (Eqs. (9), (10)). These two equations may be represented as

\[
\sigma_{y1} - \frac{\sigma_y + \sigma_z}{2} = \frac{\sigma_y - \sigma_z}{2} \cos 2\alpha + \tau_{xy} \sin 2\alpha ,
\]

\[
\tau_{y1z1} = -\frac{\sigma_y - \sigma_z}{2} \sin 2\alpha + \tau_{yz} \cos 2\alpha .
\]

Squaring each equation, adding them, and simplifying, we obtain well-known equation of a circle:

\[
\left(\sigma_{y1} - \frac{\sigma_y + \sigma_z}{2}\right)^2 + \tau_{y1z1}^2 = \left(\frac{\sigma_y - \sigma_z}{2}\right)^2 + \tau_{yz}^2 .
\]

This equation can be written in more simple form using the following notation:

\[
\sigma_{\text{aver}} = \frac{\sigma_y + \sigma_z}{2}.
\]

\[
R = \sqrt{\left(\frac{\sigma_y - \sigma_z}{2}\right)^2 + \tau_{yz}^2} .
\]

Equation (47) now becomes

\[
\left(\sigma_{y1} - \sigma_{\text{aver}}\right)^2 + \tau_{y1z1}^2 = R^2 ,
\]

which is the equation of a circle in standard algebraic form. The coordinates are \(\sigma_{y1}\) and \(\tau_{y1z1}\), the radius is \(R\) and the center of the circle has coordinates \(\sigma_{y1} = \sigma_{\text{aver}}\) and \(\tau_{y1z1} = 0\).

5.2 Mohr’s circle construction

Mohr’s circle can be plotted from Eqs. (45, 46) and (50) in two different ways. We will plot the normal stress \(\sigma_{y1}\) positive to the right and the shear stress \(\tau_{y1z1}\) positive downward, as shown in Fig. 19. The advantage of plotting shear stresses
positive downward is that the angle $2\alpha$ on Mohr’s circle is positive when counterclockwise, which agrees with the positive direction of $2\alpha$ in the derivation of the transformation equations.

Mohr’s circle can be constructed in a variety of ways, depending upon which stresses are known and which are unknown. Let us assume that we know the stresses $\sigma_y$, $\sigma_z$ and $\tau_{yz}$ acting on the $y$ and $z$ planes of an element in plane stress (Fig. 20a). This information is sufficient to construct the circle. Then, with the circle drawn, we can determine the stresses $\sigma_y$, $\sigma_z$ and $\tau_{yz}$ acting on an inclined element (Fig. 20b). We can also obtain the principal stresses and maximum shear stresses from the circle.

With $\sigma_y$, $\sigma_z$ and $\tau_{yz}$ known, the procedure for constructing Mohr’s circle is as follows (see Fig. 20c):

(a) Draw a set of coordinate axes with $\sigma_{y_1}$ as abscissa (positive to the right) and $\tau_{y_1z_1}$ as ordinate (positive downward).

(b) Locate the center $C$ of the circle at the point having coordinates $\sigma_{y_1} = \sigma_{aver}$ and $\tau_{y_1z_1} = 0$ (see Eqs. (48) and (50)).

(c) Locate point $A$, representing the stress conditions on the $y$ face of the element shown in Fig. 20a, by plotting its coordinates $\sigma_{y_1} = \sigma_y$ and $\tau_{y_1z_1} = \tau_{yz}$. Note that point $A$ corresponds to $\alpha = 0$. The $y$ face of the element (Fig. 20a) is labeled “$A$” to show its correspondence with point $A$ in the diagram.

(d) Locate point $B$ representing the stress conditions on the $z$ face of the element shown in Fig. 20a, by plotting its coordinates $\sigma_{y_1} = \sigma_z$ and $\tau_{y_1z_1} = -\tau_{yz}$. Point $B$ corresponds to $\alpha = 90^\circ$. The $z$ face of the element (Fig. 20a) is labeled “$B$” to show its correspondence with point $B$ in the diagram.

(e) Draw a line from point $A$ to point $B$. It is a diameter of the circle and passes through the center $C$. Points $A$ and $B$, representing the stresses on planes at $90^\circ$ to each other, are at opposite ends of the diameter (and therefore are $180^\circ$ apart on the circle).
(f) Using point $C$ as the center, draw Mohr’s circle though points $A$ and $B$. The circle drawn in this manner has radius $R$ (Eq. (49)).

Note. When Mohr's circle is plotted to scale, numerical results can be obtained graphically.

![Construction of Mohr's circle for plane stress](image.png)
(1) **Stresses on an inclined element.** Mohr’s circle shows how the stresses represented by points on it are related to the stresses acting on an element. The stresses on an inclined plane defined by the angle $\alpha$ (Fig. 20b) are found on the circle at the point where the angle from the reference point (point A) is $2\alpha$. Thus, as we rotate the $y_1\bar{z}_1$ axes counterclockwise through an angle $\alpha$ (Fig. 20b), the point on Mohr’s circle corresponding to the $y_1$ face moves counterclockwise through an angle $2\alpha$. Similarly, in clockwise rotation of the axes, the point on the circle moves clockwise through an angle twice as large.

(2) **Principal stresses.** The determination of principal stresses is the most important application of Mohr’s circle. As we move around Mohr’s circle (Fig. 20c), we encounter point $P_1$ where the normal stress reaches its algebraically largest value and the shear stress is zero. Hence, point $P_1$ gives the algebraically larger principal stress and its angle $2\alpha_{P_1}$ from the reference point $A$ ($\alpha = 0$) gives the orientation of the principal plane. The next principal plane, associated with the algebraically smallest normal stress, is represented by point $P_3$, diametrically opposite to point $P_1$.

(3) **Maximum shear stresses.** Points $S_1$ and $S_2$ which represent the planes of maximum positive and maximum negative shear stresses, respectively, are located at the bottom and top of Mohr’s circle (Fig. 20c). These points are at angles $2\alpha = 90^\circ$ from points $P_1$ and $P_3$, which agrees with the fact that the planes of maximum shear stress are oriented at $45^\circ$ to the principal planes. The maximum shear stresses are numerically equal to the radius $R$ of the circle. Also, the normal stresses on the planes of maximum shear stress are equal to the abscissa of point $C$, which is the average normal stress $\sigma_{aver}$.

Various multiaxial states of stress can readily be treated by applying the foregoing procedure. Fig. 21 shows some examples of Mohr's circles for commonly encountered cases. Analysis of material behavior subject to different loading conditions is often facilitated by this type of compilation. Interestingly, for the case of equal tension and compression (this type of stress state was named as pure shear) (see Fig. 21a), $\sigma_x = 0$ and the $x$-directed strain does not exist ($\varepsilon_x = 0$). Hence the element is in a state of **plane strain as well as plane stress**. An element in this condition can be converted to a condition of pure shear by rotating it $45^\circ$ as indicated.
In the case of triaxial tension (Fig. 21b and 22a), a Mohr's circle is drawn corresponding to each projection of a three-dimensional element (see Fig. 22b). The three-circle cluster represents Mohr's circle for triaxial stress. The case of tension with lateral pressure (Fig. 21c) is explained similarly.

(a) Equal tension and compression; pure shear

(b) Triaxial tension

(c) Tension with lateral pressure

Fig. 21 Mohr's circle for various states of stress

Fig. 22 Three-dimensional state of stress
Note. Mohr's circle eliminates the need to remember the formulas of stress transformation.

Example 6

At a point on the surface of a cylinder, loaded by internal pressure, the material is subjected to biaxial stresses $\sigma_y = 90\,\text{MPa}$ and $\sigma_z = 20\,\text{MPa}$, as shown on the stress element of figure (a). Using Mohr's circle, determine the stresses acting on an element inclined at an angle $\alpha = 30^\circ$. (Consider only the in-plane stresses, and show the results on a sketch of a properly oriented element).

(a) Element in plane stress; (b) stresses acting on a n element oriented at an angle $\alpha = 30^\circ$; (c) the corresponding Mohr's circle (Note: All stresses on the circle have units of MPa)
Solution (1) Construction of Mohr’s circle. Let us set up the axes for the normal and shear stresses, with $\sigma_{y_1}$ positive to the right and $\tau_{y_1z_1}$ positive downward, as shown in figure (c). Then we place the center $C$ of the circle on the $\sigma_{y_1}$ axis at the point where the stress equals the average normal stress:

$$\sigma_{\text{aver}} = \frac{\sigma_y + \sigma_z}{2} = \frac{90 \text{ MPa} + 20 \text{ MPa}}{2} = 55 \text{ MPa}.$$  

Point $A$, representing the stresses on the $y$ face of the element ($\alpha = 0$), has coordinates

$$\sigma_{y_1} = 90 \text{ MPa}, \quad \tau_{y_1z_1} = 0.$$  

Similarly, the coordinates of point $B$, representing the stresses on the $z$ face ($\alpha = 90^\circ$), are

$$\sigma_{y_1} = 20 \text{ MPa}, \quad \tau_{y_1z_1} = 0.$$  

Now we draw the circle through points $A$ and $B$ with center at $C$ and radius $R$ equal to

$$R = \sqrt{\left(\frac{\sigma_y - \sigma_z}{2}\right)^2 + \tau_{yz}^2} = \sqrt{\left(\frac{90 \text{ MPa} - 20 \text{ MPa}}{2}\right)^2 + 0} = 35 \text{ MPa}.$$  

(2) Stresses on an element inclined at $\alpha = 30^\circ$. The stresses acting on a plane oriented at an angle $\alpha = 30^\circ$ are given by the coordinates of point $D$, which is at an angle $2\alpha = 60^\circ$ from point $A$ (see figure (c)). By inspection of the circle, we see that the coordinates of point $D$ are

$$\sigma_{y_1} = \sigma_{\text{aver}} + R \cos 60^\circ = 55 \text{ MPa} + (35 \text{ MPa})(\cos 60^\circ) = 72.5 \text{ MPa},$$  

$$\tau_{y_1z_1} = -R \cos 60^\circ = -(35 \text{ MPa})(\cos 60^\circ) = -30.3 \text{ MPa}.$$  

In a similar manner, we can find the stresses represented by point $D'$, which corresponds to an angle $\alpha = 120^\circ$ (or $2\alpha = 240^\circ$):

$$\sigma_{y_1} = \sigma_{\text{aver}} - R \cos 60^\circ = 55 \text{ MPa} - (35 \text{ MPa})(\cos 60^\circ) = 37.5 \text{ MPa},$$  

$$\tau_{y_1z_1} = R \cos 60^\circ = (35 \text{ MPa})(\cos 60^\circ) = 30.3 \text{ MPa}.$$
These results are shown in figure (b) on a sketch of an element oriented at an angle $\alpha = 30^\circ$, with all stresses shown in their true directions.

**Note. The sum of the normal stresses on the inclined element is equal to** $\sigma_y + \sigma_z$ **or 110 MPa.**

**Example 7**

An element in plane stress at the surface of a structure is subjected to stresses $\sigma_y = 100 \text{ MPa}$, $\sigma_z = 35 \text{ MPa}$, and $\tau_{yz} = 30 \text{ MPa}$, as shown in figure (a). Using Mohr's circle, determine the following quantities: (1) the stresses acting on an element inclined at an angle $\alpha = 40^\circ$, (2) the principal stresses, and (3) the maximum shear stresses. Consider only the in-plane stresses, and show all results on sketches of properly oriented elements.

**Solution**  
(1) **Construction of Mohr’s circle.** Let us set up the axes for Mohr's circle, with $\sigma_{y_1}$ positive to the right and $\tau_{y_1z_1}$ positive downward (see figure (c)). The center $C$ of the circle is located on the $\sigma_{y_1}$ axis at the point where $\sigma_{y_1}$ equals the average normal stress:

$$\sigma_{\text{aver}} = \frac{\sigma_y + \sigma_z}{2} = \frac{100 \text{ MPa} + 35 \text{ MPa}}{2} = 67.5 \text{ MPa}.$$  

Point $A$, representing the stresses on the $y$ face of the element ($\alpha = 0$), has coordinates $\sigma_{y_1} = 100 \text{ MPa}$, $\tau_{y_1z_1} = 30 \text{ MPa}$.

Similarly, the coordinates of point $B$, representing the stresses on the $z$ face ($\alpha = 90$), are $\sigma_{y_1} = 35 \text{ MPa}$, $\tau_{x_1y_1} = -30 \text{ MPa}$.

The circle is now drawn through points $A$ and $B$ with center at $C$. The radius of the circle is

$$R = \sqrt{\left(\frac{\sigma_y - \sigma_z}{2}\right)^2 + \tau_{yz}^2} = \sqrt{\left(\frac{100 \text{ MPa} - 35 \text{ MPa}}{2}\right)^2 + (30 \text{ MPa})^2} = 44.2 \text{ MPa.}$$
(a) Element in plane stress; (b) stress acting on an element oriented at $\alpha = 40^\circ$; (c) the corresponding Mohr’s circle; (d) principal stresses; (e) maximum shear stresses
(2) The stresses acting on a plane oriented at an angle $\alpha = 40^\circ$. They are given by the coordinates of point $D$, which is at an angle $2\alpha = 80^\circ$ from point $A$ (see figure (c)). To calculate these coordinates, we need to know the angle between line $CD$ and the $\sigma_{y_1}$ axis (that is, angle $DCP_1$), which in turn requires that we know the angle between line $CA$ and the $\sigma_{y_1}$ axis (angle $ACP_1$). These angles are found from the geometry of the circle, as follows:

$$\tan ACP_1 = \frac{30 \text{ MPa}}{35 \text{ MPa}} = 0.857, \quad ACP_1 = 40.6^\circ,$$

$$DCP_1 = 80^\circ - ACP_1 = 80^\circ - 40.6^\circ = 39.4^\circ.$$  

Knowing these angles, we can determine the coordinates of point $D$ directly from the figure:

$$\sigma_{y_1} = 67.5 \text{ MPa} + (44.2 \text{ MPa})(\cos 39.4^\circ) = 101.65 \text{ MPa},$$

$$\tau_{y_1z_1} = -(44.2 \text{ MPa})(\sin 39.4^\circ) = -28.06 \text{ MPa}.$$  

In an analogous manner, we can find the stresses represented by point $D'$, which corresponds to a plane inclined at an angle $\alpha = 130^\circ$ (or $2\alpha = 260^\circ$):

$$\sigma_{y_1} = 67.5 \text{ MPa} - (44.2 \text{ MPa})(\cos 39.4^\circ) = +33.35 \text{ MPa},$$

$$\tau_{y_1z_1} = (44.2 \text{ MPa})(\sin 39.4^\circ) = 28.06 \text{ MPa}.$$  

These stresses are shown in figure (c) on a sketch of an element oriented at an angle $\alpha = 40^\circ$ (all stresses are shown in their true directions).

**Note. The sum of the normal stresses is equal to $\sigma_x + \sigma_y$ or 135 MPa.**

(3) Principal stresses. The principal stresses are represented by points $P_1$ and $P_2$ on Mohr's circle (see figure (c)). The algebraically larger principal stress (point $P_1$) is

$$\sigma_1 = 67.5 \text{ MPa} + 44.2 \text{ MPa} = 111.7 \text{ MPa},$$

as seen by inspection of the circle. The angle $2\alpha_{p_1}$ to point $P_1$ from point $A$ is the angle $ACP_1$ on the circle, that is,
Thus, the plane of the algebraically larger principal stress is oriented at an angle \( \alpha_p = 20.3^\circ \), as shown in figure (d).

The algebraically smaller principal stress (represented by point \( P_2 \)) is obtained from the circle in a similar manner:

\[
\sigma_2 = 67.5 \text{ MPa} - 44.2 \text{ MPa} = 23.3 \text{ MPa}.
\]

The angle \( 2\alpha_{p_2} \) to point \( P_2 \) on the circle is \( 40.6^\circ + 180^\circ = 220.6^\circ \); thus, the second principal plane is defined by the angle \( \alpha_{p_2} = 110.3^\circ \). The principal stresses and principal planes are shown in the figure (d).

**Note. The sum of the normal stresses is equal to 135 MPa.**

(4) **Maximum shear stresses.** The maximum shear stresses are represented by points \( S_1 \) and \( S_2 \) on Mohr's circle; therefore, the maximum in-plane shear stress (equal to the radius of the circle) is

\[
\tau_{\text{max}} = 44.2 \text{ MPa}.
\]

The angle \( ACS_1 \) from point \( A \) to point \( S_1 \) is \( 90^\circ - 40.6^\circ = 49.4^\circ \), and therefore the angle \( 2\alpha_{s_1} \), for point \( S_1 \) is

\[
2\alpha_{s_1} = -49.4^\circ.
\]

This angle is negative because it is measured clockwise on the circle. The corresponding angle \( \alpha_{s_1} \) to the plane of the maximum positive shear stress is one-half that value, or \( \alpha_{s_1} = -24.7^\circ \), as shown in Figs. (c) and (e). The maximum negative shear stress (point \( S_2 \) on the circle) has the same numerical value as the maximum positive stress (44.2 MPa).

The normal stresses acting on the planes of maximum shear stress are equal to \( \sigma_{\text{aver}} \), which is the abscissa of the center \( C \) of the circle (67.5 MPa). These stresses are also shown in figure (e).

**Note. The planes of maximum shear stresses are oriented at 45° to the principal planes.**
Example 8

At a point on the surface of a shaft the stresses are $\sigma_y = -50\,\text{MPa}$, $\sigma_z = 10\,\text{MPa}$, and $\tau_{yz} = -40\,\text{MPa}$, as shown in figure (a). Using Mohr's circle, determine the following quantities: (1) the stresses acting on an element inclined at an angle $\alpha = 45^\circ$, (2) the principal stresses, and (3) the maximum shear stresses.

Solution  (1) Construction of Mohr’s circle. The axes for the normal and shear stresses in the Mohr’s circle are shown in figure (c), with $\sigma_{y_1}$ positive to the right and $\tau_{y_1z_1}$ positive downward. The center $C$ of the circle is located on the $\sigma_{y_1}$ axis at the point where the stress equals the average normal stress:

$$\sigma_{\text{aver}} = \frac{\sigma_y + \sigma_z}{2} = \frac{-50\,\text{MPa} + 10\,\text{MPa}}{2} = -20\,\text{MPa}.$$ 

Point $A$, representing the stresses on the $y$ face of the element ($\alpha = 0$), has coordinates $\sigma_{y_1} = -50\,\text{MPa}$, $\tau_{y_1z_1} = -40\,\text{MPa}$.

Similarly, the coordinates of point $B$, representing the stresses on the $z$ face ($\alpha = 90^\circ$), are $\sigma_{y_1} = 10\,\text{MPa}$, $\tau_{y_1z_1} = 40\,\text{MPa}$.

The circle is now drawn through points $A$ and $B$ with center at $C$ and radius $R$ equal to:

$$R = \sqrt{\left(\frac{\sigma_y - \sigma_z}{2}\right)^2 + \tau_{xy}^2} = \sqrt{\left(\frac{-50\,\text{MPa} - 10\,\text{MPa}}{2}\right)^2 + (-40\,\text{MPa})^2} = 50\,\text{MPa}.$$ 

(2) Stresses on an element inclined at $\alpha = 45^\circ$. These stresses are given by the coordinates of point $D$, which is at an angle $2\alpha = 90^\circ$ from point $A$ (figure (c)). To evaluate these coordinates, we need to know the angle between line $CD$ and the negative $\sigma_{y_1}$ axis (that is, angle $DCP_2$), which in turn requires that we know the angle between line $CA$ and the negative $\sigma_{y_1}$ axis (angle $ACP_2$). These angles are found from the geometry of the circle as follows:

$$\tan ACP_2 = \frac{40\,\text{MPa}}{30\,\text{MPa}} = \frac{4}{3}, \quad ACP_2 = 53.13^\circ,$$

$$DCP_2 = 90^\circ - ACP_2 = 90^\circ - 53.13^\circ = 36.87^\circ.$$

V. DEMENKO  MECHANICS OF MATERIALS  2020
Lectures 2020/08 Two-dimensional (Plane) Stress State. Graphical Method of Stress State Analysis.doc
(a) Element in plane stress; (b) stresses acting on an element oriented at \( \alpha = 40^\circ \); (c) the corresponding Mohr’s circle; (d) principal stresses, and (e) maximum shear stresses. (Note: All stresses on the circle have units of MPa)
Knowing these angles, we can obtain the coordinates of point \( D \) directly from the figure:

\[
\sigma_{y1} = -20 \text{ MPa} - (50 \text{ MPa})(\cos36.87^\circ) = -60 \text{ MPa},
\]

\[
\tau_{y1z1} = (50 \text{ MPa})(\sin36.87^\circ) = 30 \text{ MPa}.
\]

In an analogous manner, we can find the stresses represented by point \( D' \), which corresponds to a plane inclined at an angle \( \alpha = 135^\circ \) (or \( 2\alpha = 270^\circ \)):

\[
\sigma_{y1} = -20 \text{ MPa} + (50 \text{ MPa})(\cos36.87^\circ) = 20 \text{ MPa},
\]

\[
\tau_{y1z1} = (-50 \text{ MPa})(\sin36.87^\circ) = -30 \text{ MPa}.
\]

These stresses are shown in Fig. b on a sketch of an element oriented at an angle \( \alpha = 45^\circ \) (all stresses are shown in their true directions).

**Note. The sum of the normal stresses is equal to \( \sigma_y + \sigma_z \) or \(-40 \text{ MPa}\).**

(3) **Principal stresses.** They are represented by points \( P_1 \) and \( P_2 \) on Mohr's circle. The algebraically larger principal stress (represented by point \( P_1 \)) is

\[
\sigma_1 = -20 \text{ MPa} + 50 \text{ MPa} = 30 \text{ MPa},
\]

as seen by inspection of the circle. The angle \( 2\alpha_{p_1} \) to point \( P_1 \) from point \( A \) is the angle \( ACP_1 \) measured counterclockwise on the circle, that is,

\[
ACP_1 = 2\alpha_{p_1} = 53.13^\circ + 180^\circ = 233.13^\circ, \quad \alpha_{p_1} = 116.6^\circ.
\]

Thus, the plane of the algebraically larger principal stress is oriented at an angle \( \alpha_{p_1} = 116.6^\circ \).

The algebraically smaller principal stress (point \( P_2 \)) is obtained from the circle in a similar manner:

\[
\sigma_3 = -20 \text{ MPa} - 50 \text{ MPa} = -70 \text{ MPa}.
\]

The angle \( 2\alpha_{p_2} \) to point \( P_2 \) on the circle is 53.13°. The second principal plane is defined by the angle \( 2\alpha_{p_2} = 26.6^\circ \).

**Note. The sum of the normal stresses is equal to \( \sigma_y + \sigma_z \) or \(-40 \text{ MPa}\).**
(4) **Maximum shear stresses.** The maximum positive and negative shear stresses are represented by points $S_2$ and $S_2$ on Mohr's circle (figure (c)). Their magnitudes, equal to the radius of the circle, are

$$\tau_{\text{max}} = 50 \text{MPa}.$$  

The angle $ACS_1$ from point $A$ to point $S_1$ is $90^\circ + 53.13^\circ = 143.13^\circ$, and therefore the angle $2\alpha_{S_1}$ for point $S_1$ is

$$2\alpha_{S_1} = 143.13^\circ.$$  

The corresponding angle $\alpha_{S_1}$ to the plane of the maximum positive shear stress is one-half that value, or $\alpha_{S_1} = 71.6^\circ$, as shown in figure (e). The maximum negative shear stress (point $S_2$ on the circle) has the same numerical value as the positive stress (50 MPa).

The normal stresses acting on the planes of maximum shear stress are equal to $\sigma_{\text{aver}}$, which is the coordinate of the center $C$ of the circle ($-20\text{MPa}$). These stresses are also shown in figure (e).

**Note.** The planes of maximum shear stress are oriented at $45^\circ$ to the principal planes.

### 6 Examples of Simplified Analytical and Graphical Solutions of the Problems of Plane Stress State

#### 6.1 Direct problem of plane stress state. Determination of stresses on inclined planes

**Example 1**

![Stress Diagram](image)

**Given:** $\sigma_1 = 80\text{MPa}$, $\sigma_2 = 20\text{MPa}$.

It is necessary to determine the stresses on the plane of general position with the normal at $\alpha = +30^\circ$ relative to $\sigma_1$ direction and also the stresses on perpendicular plane.

**Analytical solution**

$$\sigma_\alpha = \sigma_1 \cos^2 \alpha + \sigma_2 \sin^2 \alpha =$$
\[ (80) \cos^2(30^\circ) + (20) \sin^2(30^\circ) = \]
\[ = 80 \left( \frac{\sqrt{3}}{2} \right)^2 + 20 \left( \frac{1}{2} \right)^2 = +65 \text{ MPa}, \]
\[
\sigma_\beta = \sigma_1 \sin^2 \alpha + \sigma_2 \cos^2 \alpha = (80) \sin^2(30^\circ) + (20) \cos^2(30^\circ) = \\
= 80 \left( \frac{1}{2} \right)^2 + 20 \left( \frac{\sqrt{3}}{2} \right)^2 = +35 \text{ MPa}. \]

Checking:
\[
\sigma_1 + \sigma_2 = \sigma_\alpha + \sigma_\beta, \\
(80 + 20 = 65 + 35), \\
\tau_\alpha = \frac{\sigma_1 - \sigma_2}{2} \sin 2\alpha = \frac{(80) - (20)}{2} \sin(60^\circ) = +26 \text{ MPa}, \\
\tau_\beta = -\tau_\alpha = -26 \text{ MPa}. \]

**Graphical solution using Mohr’s circles.**

**Given:** stresses on the faces of the element are described by two points lying on the diameter of Mohr’s circle in system of coordinates \((\sigma, \tau)\): point \(A (\sigma_1,0)\), point \(B (\sigma_2,0)\).

It is necessary to determine the coordinates of the point \(C (\sigma_\alpha, \tau_\alpha)\) and point \(D (\sigma_\beta, \tau_\beta)\), which belong to the diameter of the Mohr’s circle.
Example 2

**Given:** Stress state of the element is described by the stresses on two mutually perpendicular planes:

\[ \sigma_1 = 400 \text{ MPa}, \quad \sigma_3 = -400 \text{ MPa}. \]

It is necessary to determine the stresses on the plane of general position with the normal at \( \alpha = -45^\circ \) relative to direction of \( \sigma_1 \).

**Analytical solution**

\[
\sigma_\alpha = \sigma_1 \cos^2 \alpha + \sigma_3 \sin^2 \alpha = (+400)\cos^2(-45^\circ) + (-400)\sin^2(-45^\circ) = 0,
\]

\[
\sigma_\beta = \sigma_1 \sin^2 \alpha + \sigma_3 \cos^2 \alpha = (+400)\sin^2(-45^\circ) + (-400)\cos^2(-45^\circ) = 0.
\]

Checking:

\[
\sigma_1 + \sigma_3 = \sigma_\alpha + \sigma_\beta,
\]

\[ (+400 - 400 = 0 + 0), \]

\[
\tau_\alpha = \frac{\sigma_1 - \sigma_3}{2} \sin 2\alpha = \frac{(+400) - (-400)}{2} \sin(-90^\circ) = -400 \text{ MPa},
\]

\[ \tau_\beta = -\tau_\alpha = +400 \text{ MPa}. \]

**Graphical solution using Mohr’s circle**

**Given:** stresses on the faces of the element are represented by two points lying on the diameter of the Mohr’s circle: point \( A (\sigma_1,0) \), point \( B (\sigma_3,0) \).

It is necessary to determine coordinates of the point \( C (\sigma_\alpha, \tau_\alpha) \) and point \( D (\sigma_\beta, \tau_\beta) \), lying on the diameter of Mohr’s circle inclined at the angle \( 2\alpha = -90^\circ \) (clockwise rotation).
6.2 Inverse problem of plain stress state. Determination of principal planes position and values of principal stresses

Example 3

Given:

\[
\begin{align*}
\sigma_\alpha &= 65 \text{ MPa} \\
\sigma_\beta &= 35 \text{ MPa}, \\
\sigma_\alpha &> \sigma_\beta, \\
\tau_\alpha &= 26 \text{ MPa}.
\end{align*}
\]

It is necessary to find principal stresses and position of principal planes, i.e.

\[
\alpha_p - \text{?} \quad \sigma_{\text{max}} - \text{?}
\]

**Analytical solution**

1. Position of principal plane is determined by the angle

\[
tg 2\alpha_0 = \frac{-2\tau_\alpha}{\sigma_\alpha - \sigma_\beta} = \frac{-2(26)}{(65)-(35)} = \frac{-52}{30} = -1.73,
\]

\(\alpha_p = -30^\circ\). Note, that \(\alpha_p\) should be originated from \(\sigma_\alpha\) direction and to be clockwise.

\[
\sigma_{\text{max}} = \sigma_\alpha + \sigma_\beta + 1 \frac{1}{2} \sqrt{(\sigma_\alpha - \sigma_\beta)^2 + 4\tau_\alpha^2} = \\
= \frac{(65)+(35)}{2} \pm \sqrt{((65)-(35))^2 + 4(26)^2} = 50 \pm 30 \text{ MPa}
\]

\(\sigma_1 = 80 \text{ MPa}, \quad \sigma_2 = 20 \text{ MPa}\).

**Graphical solution**

Given:

point \(M (\sigma_\alpha, \tau_\alpha)\) and point \(N (\sigma_\beta, \tau_\beta)\), which belong to Mohr’s circle and are lying on its diameter.

It is necessary to determine position of the point \(K (\sigma_1,0)\) and point \(L (\sigma_2,0)\), also lying on the Mohr’s circle and belonging to its diameter. Solution is evident from the Fig.
